Abstract—Isothermal vapor liquid equilibria for the binary system of ethylene glycol monopropyl ether with 2,2-dimethylbutane and 2,3-dimethylbutane were measured in a circulating water bath at 303.15, 318.15, and 333.15 K. The apparatus was in-house designed and manufactured. Consistency testing of the apparatus was done by comparing the measured vapor pressures to the calculated vapor pressures from the Antoine equation. The measured systems were correlated with a Peng-Robinson equation of state (PR) combined with Wong-Sandler mixing rule for the vapor phase, and NRTL, UNIQUAC, and Wilson activity coefficient models for the liquid phase. All the measured systems showed good agreement with the correlation results.

Key words: Vapor-liquid Equilibria, Surfactant, Ethylene Glycol Monopropyl Ether, 2,2-Dimethylbutane, 2,3-Dimethylbutane

INTRODUCTION

Surfactants are industrially important materials because of their wide ranging applications in the petrochemical, pharmaceutical, agrichemical and cosmetic industries. For these applications, measuring the phase behavior of surfactants and their mixtures is very important. Prediction of phase behavior is difficult for alkoxy ethanol, which includes both ether (O) and hydroxyl (OH) groups in the one molecule, since the simultaneous presence of both groups causes intra-molecular self-association and inter-molecular association for the mixtures of alkoxy ethanol and hydrocarbons or alcohols. Extensive phase behavior data are available for alkoxy ethanol+water [1-4], whereas little data are available for mixtures of alkoxy ethanol and hydrocarbons [5,6] or alcohols [7]. Previously, we measured vapor liquid equilibria (VLE) for the binary systems of hydrocarbons with surfactants [e.g., ethylene glycol monopropyl ether (C3E1) or ethylene glycol isopropyl ether (*i*C3E1)] [8-10] and alcohols with C3E1 systems [11] at isothermal or isobaric condition, to investigate the branch effect of hydrocarbons or alcohols in the alkoxy ethanol mixture.

In this work, to study the branch effect of hexane isomer in the C3E1 mixture, we measured the VLE for the binary system of ethylene glycol monopropyl ether with 2,2-dimethylbutane and 2,3-dimethylbutane at three constant temperatures: 303.15K, 318.15 K and 333.15 K. The measured systems were correlated with the Peng-Robinson equation of state (PR) [12] combined with the Wong-Sandler mixing rule [13] for the vapor phase, and NRTL [14], UNIQUAC [15], and Wilson [16] activity coefficient models for the liquid phase.

EXPERIMENTAL SECTION

1. Chemicals

2,2-Dimethylbutane and C3E1 were supplied by Sigma Aldrich (U.S.A.) and 2,3-dimethylbutane was supplied by Tokyo Chemical Industry (Japan). The minimum purity exceeded 99% (GC grade) for 2,2-dimethylbutane and 2,3-dimethylbutane, and was 99.4% (GC grade) for C3E1. These materials were used without further purification because no other peaks were detected in the gas chromatography (GC) analysis.

2. Apparatus and Procedure

The apparatus (Fig. 1) was designed and manufactured. The designed metal cell was connected to a pressure sensor, temperature sensor, vacuum pump, and feed chamber through a fitting, and was installed in a circulating water bath. The material of the designed cylindrical metal cell was stainless ‘Sus 316’, and the inner volume

was about 125 ml. The pressure sensor was supplied by Honeywell and the values were measured by a digital indicator, supplied by Red Lion, with an uncertainty of 0.11 kPa. The temperatures were measured using a thermometer supplied by Fluke with an uncertainty of 0.005 K. The uncertainties of the pressure and the temperature sensor were provided from the manufacturer. The circulating water bath that was controllable to 0.01 K was provided by Polyscience, the vacuum pump by Woosung Vacuum, and the trap by Daihan Scientific. The valves (female type) used in fitting of the cell were supplied by Swagelok (6LVV-DPRFR4-P), and were manufactured for very low pressure.

First, we fed the components to the cell from the feed chamber after degassing. The cell was then placed in the circulating water bath and the temperature was set to the desired value. The system was considered to have reached phase equilibrium when the pressure fluctuated within 0.1 kPa during every 15 minutes. The equilibrium pressure was obtained by repeating measurements 3–5 times, and the readings were averaged. After measuring the equilibrium pressure at the other specified temperatures, we sampled the small portion of liquid phase from the cell using a syringe. The samples were analyzed by GC with an installed thermal conductivity detector and a Porapak Q column (length: 1.83 m, diameter: 3.18 mm, mesh range: 80/100) with helium as a carrier gas. Finally, the composition was changed and the entire procedure was repeated.

RESULTS AND DISCUSSION

Isothermal VLE was measured for the binary systems of ethylene glycol monopropyl ether with 2,2-dimethylbutane and 2,3-dimethylbutane at constant temperatures of 303.15, 318.15, and 333.15 K. The systems were measured by static method. Results (\pm standard deviation) are displayed in Tables 1 and 2. The experimental points were measured more than three times and each series of values was averaged. Expanded uncertainties, U, and coverage factor, k, of the results are presented in Table 3, and were calculated from NIST

uncertainty guidelines [17]. According to the guidelines, accuracy, readability and repeatability of the indicator and accuracy of the probe were used for the temperature and the pressure. Also, readability, repeatability and non-linearity of GC calibration were used for the liquid phase composition.

The vapor pressures of pure components were calculated from the Antoine equation and the constants, obtained from NIST web data [18], are presented in Table 4. The measured vapor pressures were compared to the calculated vapor pressure. As shown in Table 4, the deviations of the measured and calculated vapor pressures were $<1\%$, indicating that the cell was suitable for the experiment. Comparison between measured and calculated vapor pressures for ethylene glycol monopropyl ether is not given here, because the vapor pressure was too low to adequately compare. Also, the temperature range of the Antoine constants deviated from the system temperature.

The measured data were correlated using the PR EOS [12], combined with conventional mixing rule, expressed as Eq. (2), for the vapor phase. For the liquid phase, the PR model combined with

$$\text{Deviation (\%)} = \left| \frac{P^{\text{exp}} - P^{\text{cal}}}{P^{\text{exp}}} \right| \times 100$$

Wong-Sandler mixing rule [13], expressed as Eq. (6), including activity coefficient models, NRTL, UNIQUAC, and Wilson, was used.

The fugacity coefficient for the vapor phase was introduced in Peng and Robinson [12], and was expressed as:

$$\ln \varphi_i^v = \frac{b_i}{b} (z-1) - \ln(z-B) - \frac{A}{2\sqrt{2}B} \left(\frac{2 \sum_k x_k a_{ik}}{a} - \frac{b_i}{b} \right) \ln \frac{z+(1+\sqrt{2})B}{z+(1-\sqrt{2})B} \quad (1)$$

where A and B are defined as:

$$A = \frac{Pa}{(RT)^2} \quad B = \frac{Pb}{RT} \quad (2)$$

$$a = \sum_i \sum_j x_i x_j a_{ij} \quad b = \sum_i x_i b_i \quad (3)$$

The parameters used in this correlation are presented in Table 5. The critical points, T_c , P_c , and boiling points, T_b , were obtained from NIST web data [18], and the acentric factor, ω , was obtained from the DIPPR database [19].

The fugacity coefficient for the liquid phase [13] is expressed as:

$$\ln \varphi_i^l = \frac{1}{b_m} \left(\frac{\partial n b_m}{\partial n_i} \right) (z-1) - \ln(z-B) - \frac{A}{2\sqrt{2}B} \times \left(\frac{1}{a_m} \left(\frac{1}{n} \frac{\partial n^2 a_m}{\partial n_i} \right) - \frac{1}{b_m} \left(\frac{\partial n b_m}{\partial n_i} \right) \right) \ln \frac{z+(1+\sqrt{2})B}{z+(1-\sqrt{2})B} \quad (4)$$

where A and B are defined as:

$$A = \frac{Pa_m}{(RT)^2} \quad B = \frac{Pb_m}{RT} \quad (5)$$

$$\frac{a_m}{RT} = Q \frac{D}{(1-D)} \quad b_m = \frac{Q}{(1-D)} \quad (6)$$

and where Q and D are defined as:

$$Q = \sum_i \sum_j x_i x_j \left(b - \frac{a}{RT} \right)_{ij} \quad D = \sum_i x_i \frac{a_i}{b_i RT} + \frac{A_\infty^E}{CRT} \quad (7)$$

and where C and A_∞^E are defined as:

$$C = \frac{1}{\sqrt{2}} \ln(\sqrt{2}-1) \quad (8)$$

$$\frac{A_\infty^E}{RT} = \sum_i x_i \left(\frac{\sum_j x_j \tau_{ji} g_{ji}}{\sum_k x_k g_{ki}} \right). \quad (9)$$

The partial derivatives of a_m and b_m are expressed as:

$$\frac{1}{RT} \left(\frac{1}{n} \frac{\partial n^2 a_m}{\partial n_i} \right) = D \frac{\partial n b_m}{\partial n_i} + b_m \frac{\partial n D}{\partial n_i} \quad (10)$$

$$\frac{\partial n b_m}{\partial n_i} = \frac{1}{(1-D)} \left(\frac{1}{n} \frac{\partial n^2 Q}{\partial n_i} \right) - \frac{Q}{(1-D)^2} \left(1 - \frac{\partial n D}{\partial n_i} \right) \quad (11)$$

where the partial derivatives Q and D are expressed as:

$$\left(\frac{1}{n} \frac{\partial n^2 Q}{\partial n_i} \right) = 2 \sum_j x_j \left(b - \frac{a}{RT} \right)_{ij} \quad (12)$$

$$\frac{\partial n D}{\partial n_i} = \frac{a_i}{b_i RT} + \frac{\ln \gamma_{xi}}{C} \quad (13)$$

where, in order to obtain $\ln \gamma_{xi}$, NRTL, UNIQUAC, and Wilson activity coefficient models were used. As shown in Table 6, the area parameter, q, the volume parameter, r, the liquid molar volume, and the binary energy parameter, α_{ij} , were indicated. The parameters, q

^bBinary interaction parameter

^cAverage absolute deviation of the pressure

binary parameter, α_{ij} , was fixed at 0.3 in most available vapor-liquid equilibrium data, it can be fixed at 0.47 when the mixture includes strong self-associated substance. Thus, in our previous studies including ethylene glycol monopropyl ether, the α_{ij} was fixed at 0.47. However, in this work, the calculation result displayed a better agreement when the α_{ij} was fixed at 0.3. Thus, we presently used 0.3 for the α_{ij} values.

The results of the correlations are summarized in Table 7 with average absolute deviations of pressure (AADP) and interaction parameters for each system and activity model. The excess Gibbs free energy for all systems was regressed and optimized by following objective function:

$$\text{OBJ} = \sum_{i=1}^N \left| \frac{P_i^{\text{exp}} - P_i^{\text{cal}}}{P_i^{\text{exp}}} \right|. \quad (14)$$

As shown in Table 7, almost all the AADP values obtained by the NRTL and Wilson activity models were <1%, but the values obtained by UNIQUAC activity model were not. Generally, the performance of the NRTL model is the best among the NRTL, UNIQUAC, and Wilson activity coefficient models. However, the Wilson activity model presently gave the best results (Figs. 2 and 3). In these phase diagram, the experimental data were compared to each correlated model. As shown in figures, the correlated results displayed good agreement with the experimental data. Moreover,

the solid curves calculated by the PR-WS-Wilson model, showed the best results, especially at the light component-rich region.

CONCLUSION

Isothermal VLE data were measured at 303.15, 318.15, and 333.15 K for the 2,2-dimethylbutane+ethylene glycol monopropyl ether and 2,3-dimethylbutane+ethylene glycol monopropyl ether systems. Consistency of the manufactured cell was verified through the comparison of the measured vapor pressure to the calculated values. The manufactured cell was suitable for the study, because the deviations of vapor pressures were <1%.

Correlations of the measured data were made by using the PR EOS model combined with conventional mixing rule for the vapor phase, and the PR model combined with the Wong-Sandler mixing rule including NRTL, UNIQUAC, and Wilson activity coefficient models was used for the liquid phase. Overall, the calculated model showed a good agreement with the experimental data, with the Wilson model being superior, especially at the light component-rich region.
